Chapter 1

Introduction

This document describes the Hume programming language. *Hume* (Higher-order Unified Meta-Environment) is a strongly typed, functionally-based language with an integrated tool set for developing, proving and assessing concurrent, resource-limited systems, such as embedded or safety-critical systems. It aims to extend the frontiers of language design for such systems, introducing new levels of abstraction and provability.

Hume is named for the Scottish Enlightenment sceptical philosopher David Hume (1711-1776), who counselled that:

To begin with clear and self-evident principles, to advance by timorous and sure steps, to review frequently our conclusions, and examine accurately all their consequences; though by these means we shall make both a slow and a short progress in our systems; are the only methods, by which we can ever hope to reach truth, and attain a proper stability and certainty in our determinations.

D. Hume, An Enquiry Concerning Human Understanding, 1748

These sentiments epitomise the philosophy of programming language design that has been followed in this document.

This report is structured as follows: the remainder of this chapter provides motivation and general background; Chapter 2 is an overview of the Hume language design, including detailed informal descriptions of the process and coordination sub-languages; future chapters will cover implementation and cost modelling. Appendix A describes the concrete syntax; Appendix B is the formal static semantics, including the type system and Appendix C gives the formal dynamic semantics. Finally Appendix D defines the Hume standard prelude.

Appendix D

Standard Prelude

Summary of Standard Hume Functions and Operators

Operations on *int p* types

```
+, -, *, div, ** :: Int -> Int -> Int  
==, !=, <, <, >, > :: Int -> Int -> Bool
```

Operations on *nat p* types

```
+, -, *, div, ** :: Int -> Int -> Int  
==, !=, <, <, >, > :: Int -> Int -> Bool
```

Operations on *word p* types

```
+, -, *, /, ** :: Word -> Word -> Word  
==, !=, <, <, >, > :: Word -> Word -> Bool  
rotl, rotr, lshl, lshr :: Word -> Nat -> Word
```

Operations on *float p* types

```
+, -, *, /, ** :: Float -> Float -> Float  
sin, cos, tan, atan, acos, atan, log, exp, sqrt,  
ln, log10, sinh, cosh, tanh :: Float -> Float  
atan2 :: Float -> Float -> Float  
==, !=, <, <, >, > :: Float -> Float -> Bool
```

Operations on vector types

```
length :: <<a>> -> Int  
@ :: <<a>> -> Int -> a  
vedef :: Int -> (Int -> a) -> <<a>>  
vecmap :: <<a>> -> (a -> b) -> <<b>>  
vecfoldr :: <<a>> -> b -> (a -> b) -> b  
update :: <<a>> -> Int -> a -> <<a>>  
==, !=, <, <, >, > :: <<a>> -> <<a>> -> Bool
```

C.7 Dynamic Semantics: The Initial Environment

The initial environment comprises definitions for all functions and constructors defined in the module *Prelude*. These values must be available in all Hume programs. The meanings of other *Prisade* functions is defined by reference to Appendix D, which provides a source language definition. We assume that the meaning of basic operations (such as addition on numbers) is obvious. To define this formally would be tedious in the extreme. We will also assume without formal specification that the initial environment for some Hume program will include definitions for those functions and values that are imported into a Hume program, whether or not these were originally defined in Hume (i.e. whether or not they are “foreign” functions).

The initial environment contains the following functions (*BusVal*)

$$\begin{aligned} \text{PrimPlusInt} &\rightsquigarrow (a, b) \rightarrow a + b & \text{+ is fixed-precision integer addition} \\ \text{PrimMultInt} &\rightsquigarrow (a, b) \rightarrow a \times b & \times is fixed-precision integer multiplication \end{aligned}$$

plus the standard constructors (*BusCon*):

$$0, 1, \dots, 0.0, 0.1, \dots, \text{'True}, \text{'False}, \text{'n}, \dots, \{\}, \text{Nil}$$

The characters correspond to those defined by the ASCII character set. The mapping from syntactic variables to semantic constructors is the obvious one, that is, $E_0(\text{SetEnv}) = \text{SetEnv} \dots$

1.1 Motivation and objectives

Since the focus of the Hume design is on high reliability applications (such as safety critical or embedded systems), it is paramount that Hume programs have predictable and, preferably, provable properties. However, the strong properties of program equivalence, termination and time and space use are undecidable for Turing computable languages. Conversely, languages in which such properties are decidable (i.e. finite state machines) lack expressiveness. The goal of the Hume language design is to support a high level of expressive power, whilst providing strong guarantees of dynamic behavioural properties such as execution time and space usage.

Program proof and manipulation are greatly eased by abstractness as well as by succinctness. In particular, it is relatively hard to construct formal theories for imperative language constructs, where fine ordering greatly complicates reasoning about programs. However, programs are ultimately intended to realise solutions to concrete problems on physical computers. Increased abstractness in languages, in particular away from modifiable state, tends to greater distance from the von Neumann paradigm, with corresponding complications and efficiency losses in implementations. The Hume design contributes the desirable properties of abstraction and succinctness that are provided by a good functional programming language with a coordination language that explicitly captures time and space behaviour. Runtime efficiency is maintained through careful language design with a view to straightforward implementation on conventional computer architectures or embedded systems.

Where formal theories can be constructed, their static application to non-trivial programs is characterised by poor scalability through exponential growth in the space of properties to be explored. Alternatively, accuracy is lost through simplifying assumptions and heuristics. Dynamic evaluation of programs through instrumentation and profiling suffers from similar limitations. Typically, the volume of test data and the time required for exhaustive empirical exploration of program behaviour is prohibitive, both growing rapidly with the fineness of granularity at which exploration is conducted. Contrariwise, accuracy is lost at coarser granularity or with non-exhaustive testing.

Hume reflects these considerations in:

- the separation of the *expression* and *coordination* aspects of the language;
- the provision of an integrated *tool set*, spanning both static and dynamic program analysis and manipulation.

1.1.1 Important Design Characteristics

In general, high reliability systems must meet both strong correctness criteria and strict performance criteria. The latter are most easily attained by working at a low level, whereas the former are most easily attained by working at a high level. A primary objective of the Hume design is to allow both types of criteria to be met while working at a high level of abstraction.

The language has been designed to allow relatively simple formal cost models to be developed, capable of costing both space and time usage. This requires some restrictions on the expression language in cases which are cost or space critical. The first version of the language is deliberately rather sparse, allowing experimentation with essential features but omitting some desirable syntax or other language features, such as overlunched polymorphic types. Future versions of the language should address these omissions. The language definition does support a wide range of (particularly numeric) basic types. This is because issues of type coercion and type safety are fundamental to ensuring both correctness and security.

Both system level and process level exceptions are supported, including the ability to set timeouts for expression computations. Exceptions may be raised from within the expression language but

can only be handled by the process language. This reduces the cost of handling exceptions and maintains a pure expression language, as well as simplifying the expression cost calculus.

A radical design decision for high reliability systems is the use of automatic memory management techniques. Automatic memory management has the advantage of reducing errors due to poor manual management of memory. The disadvantage lies in terms of excessive time or space usage. Hume implementations will use static analysis tools to limit space usage, and will incorporate recent developments in bounded-time memory management techniques.

1.2 Language Structure

In common with other coordination language approaches such as Linda [7], Hume takes a layered approach. The outermost layer is a static *declaration language* that provides definitions of types, streams etc. to be used in the dynamic parts of the language. The innermost layer is a conventional *expression language* which is used to define values and (potentially higher-order) functions. Finally, the middle layer is a coordination language that links functions into possibly concurrent processes.

1.2.1 The Hume Expression Language

The Hume *expression language* is a purely functional, primitive recursive language with a strict semantics. It is intended to be used for the description of single, one-shot, non-reentrant processes. The expression language has statically provable properties of:

1. *determinism*;

2. *termination*, and

3. *bounded time and space behaviour*

through the provision of appropriate type systems and semantics (Appendices B and C).

Note that the expression language has no concept of external, imperative state. Such state considerations are encapsulated entirely within the coordination language.

1.2.2 The Hume Coordination Language

The Hume *coordination language* is a finite state language for the description of multiple, interacting, re-entrant processes built from the purely functional expression layer. The coordination language is designed to have statically provable properties that include both *process equivalence* and *safety* properties such as the absence of deadlock, livelock or resource starvation. The coordination language also inherits properties from the expression language that is embedded within it.

The basic unit of coordination is the *box*, an abstract notion of a process that specifies the links between its input and output channels in terms of functional expressions, and which provides exception handling facilities including timeouts and system exceptions. The coordination language is responsible for interaction with external, imperative state through streams and ports that are ultimately connected to external devices.

1.3 Tools to Support the Hume Language

We envisage the construction of a number of tools to support Hume programmers. By *tools* we understand formal definitions and calculi, as well as software language processors such as compilers, interpreters, type checkers etc. The tools we intend to produce are:

$$v \equiv <> \quad E \vdash \text{exp} \Rightarrow v'$$

$$\frac{}{E, v \models \{ () \rightarrow \text{exp} \} \Rightarrow v'} \quad (139)$$

$$\frac{\forall i, 0 \leq i \leq n, \text{var}_i \notin (\bigcup_{j=1}^n \text{fv}(\text{put}_j) \cup \text{fv}(\text{exp}))}{v \models \{ (\text{var}_1, \dots, \text{var}_n) \rightarrow \dots \}} \quad (140)$$

$$\frac{E, v \models \left\{ \begin{array}{l} (\text{var}_1, \dots, \text{var}_n) \rightarrow \dots \\ \text{case var}_i \text{ of } \{ \text{pat}_1 \rightarrow \dots \\ \dots \\ \text{case var}_n \text{ of } \{ \text{pat}_n \rightarrow \text{exp} \} \dots \} \end{array} \right\} \Rightarrow v'}{E, v \models \{ (\text{var}_1, \dots, \text{var}_n) \rightarrow \text{exp} \} \Rightarrow v'} \quad (141)$$

$$\frac{v \models \{ (\text{var}_1, \dots, \text{var}_n) \} \quad E \oplus \bigcup_{i=1}^n \{ \text{var}_i \rightarrow \text{v}_i \} \vdash \text{exp} \Rightarrow v'}{E, v \models \{ (\text{var}_1, \dots, \text{var}_n) \rightarrow \text{exp} \} \Rightarrow v'} \quad (142)$$

C.6.1 Exception Handler Matches

Rules 142-143 match against sequences of exception handlers.

$$\frac{E, v \models \text{handler} \Rightarrow \{ \} \quad E, v \models \text{handlers} \Rightarrow v'}{E, v \models \text{handler} \mid \text{handlers} \Rightarrow v'} \quad (143)$$

$$\frac{v \models \{ \text{exnid}, v' \} \quad E, v' \models \text{pat} \Rightarrow v''}{E, v \models \text{exnid pat} \rightarrow \text{exp} \Rightarrow v''} \quad (144)$$

$$\frac{E, v \models \text{exnid pat} \rightarrow \text{exp} \Rightarrow \{ \}}{E, v \models \text{exnid pat} \rightarrow \text{exp} \Rightarrow v} \quad (145)$$

Finally, rules 144-145 handle matches against individual exceptions, either success or failure.

Rule (133) simplifies matches into matches of the form { pat \rightarrow exp | var \rightarrow exp' }.

$$\forall i, 1 \leq i \leq n, \text{ var}_i \notin \left(\bigcup_{j=1}^n \text{fv}(\text{pat}_j) \cup \text{fv}(\text{exp}_j) \right)$$

$$\frac{\begin{array}{c} \text{pat}_1 \rightsquigarrow \text{exp}_1 \\ \vdots \\ \text{var}_i \rightsquigarrow \text{case var}_i \text{ of } \{ \\ \quad \text{pat}_{i+1} \rightsquigarrow \text{exp}_{i+1} \\ \quad \vdots \\ \quad \text{var}_n \rightsquigarrow \text{case var}_n \text{ of } \{ \\ \quad \quad \vdots \\ \quad \quad \text{var}_{n-1} \rightsquigarrow \text{case var}_{n-1} \text{ of } \{ \text{pat}_n \rightsquigarrow \text{exp}_n \dots \} \} \end{array}}{\text{E}, \text{v} \models \{ \text{pat}_1 \rightsquigarrow \text{exp}_1 \dots \mid \text{pat}_n \rightsquigarrow \text{exp}_n \} \Rightarrow \text{v}'} \quad n \geq 1 \quad (133)$$

Rules (134), (135) define the semantics of wildcard and variable matches.

$$\frac{\begin{array}{c} \text{E} \vdash \text{exp} \Rightarrow \text{v}' \\ \text{E}, \text{v} \models \{ \text{pat} \rightsquigarrow \text{exp} \} \Rightarrow \text{v}' \end{array}}{\text{E} \stackrel{*}{\vdash} \{ \text{var} \rightsquigarrow \text{v} \} \vdash \text{exp} \Rightarrow \text{v}'} \quad (134)$$

$$\frac{\text{E} \stackrel{*}{\vdash} \{ \text{var} \rightsquigarrow \text{v} \} \vdash \text{exp} \Rightarrow \text{v}'}{\text{E} \oplus \{ \text{var} \rightsquigarrow \text{v} \} \vdash \text{exp} \Rightarrow \text{v}'} \quad (135)$$

Rules (136), (140) define the semantics of matches against constructor patterns. Rules (136) and (140) are simplification rules, simplifying general constructor matches and tuple matches, respectively; the remaining rules define the matching semantics. The simplification rules are used to simplify deep pattern matches (such as [1,2]) into single-level matches,

$$\forall i, 1 \leq i \leq n, \text{ var}_i \notin \left(\bigcup_{j=1}^n \text{fv}(\text{pat}_j) \cup \text{fv}(\text{exp}_j) \right)$$

$$\frac{\text{E}, \text{v} \models \left\{ \begin{array}{c} \text{con var}_1 \dots \text{var}_n \rightsquigarrow \dots \\ \text{case var}_1 \text{ of } \{ \text{pat}_1 \rightsquigarrow \dots \\ \quad \vdots \\ \quad \text{case var}_n \text{ of } \{ \text{pat}_n \rightsquigarrow \dots \text{exp}_n \} \dots \} \end{array} \right\} \Rightarrow \text{v}'}{\text{E}, \text{v} \models \{ \text{con pat}_1 \dots \text{pat}_n \rightsquigarrow \text{exp} \} \Rightarrow \text{v}'} \quad (136)$$

$$\frac{\text{v} = \text{con} < \text{v}_1, \dots, \text{v}_n > \quad \text{E} \stackrel{*}{\vdash} \{ \forall i, 1 \leq i \leq n, \text{ var}_i \rightsquigarrow \text{v}_i \} \vdash \text{exp} \Rightarrow \text{v}'}{\text{E}, \text{v} \models \{ \text{con var}_1 \dots \text{var}_n \rightsquigarrow \text{exp} \} \Rightarrow \text{v}'} \quad (137)$$

$$\frac{\text{v} \neq \text{con} \{ \text{v}_1, \dots, \text{v}_n \} \quad \text{E}, \text{v} \models \{ \text{con var}_1 \dots \text{var}_n \rightsquigarrow \text{exp} \} \Rightarrow \text{FAIL}}{\text{E}, \text{v} \models \{ \text{con var}_1 \dots \text{var}_n \rightsquigarrow \text{exp} \} \Rightarrow \text{FAIL}} \quad (138)$$

- the Hume language definition: syntax, types and semantics;

- the Hume abstract machine(HAM)/abstract machine code(HAMC): syntax, types and semantics;

- a compiler from Hume source \rightarrow HAMC supporting separate compilation;

- a compiler from HAMC \rightarrow native assembler code.

The Hume language semantics tools comprise:

- operational semantics ... reference interpreter;
- axiomatic semantics ... correctness prover;
- termination semantics ... termination prover;
- specification notation ... refinement calculus;
- rule checker ... literate specification;
- cost calculus ... cost analyser;
- transformation system.

The abstract machine tools comprise:

- the interpreter including a profiler and instrumentor;
- a transformation system.

- the HAMC to native assembly code tools include: the run-time system; a profiler; and an instrumentor.

1.4 The Hume Research Programme

Our intention is for the Hume design to proceed in a series of planned stages.

Our immediate priorities are:

- the core language definition - syntax, types & type system, and operational semantics;
- a reference interpreter;
- a set of reference Hume programs.

We will then develop the HAM/HAMC formal definition a HAMC interpreter, and a Hume \rightarrow HAMC compiler, using the reference programs to ensure behavioural consistency with the reference interpreter.

We will next consider the cost/termination calculi systems; the profiler/instrumentor; and the program transformer; and use them to analyse the reference program set.

We envisage native code compilation, proof specification, and refinement as longer term objectives. We see proof of formal properties of language processing tools as central to this programme, notably,

1. consistency with the Hume definition;
2. preservation of the meaning and behaviour of Hume programs.

1.4.1 Status of the Research

The Hume research programme is an ongoing process, and the language design is still slowly evolving. The majority of the design has now been fixed and tested, however, and we are making progress on isolating the remaining research issues. The initial design decisions have generally proved to be robust ones and we have thus made fairly rapid progress on our research agenda. As of March 2004, we have constructed the core Hume language definition, a reference interpreter and a set of reference programs. We have provided a static semantics for types and an axiomatic dynamic semantics (both included in this definition), plus an operational semantics reflecting stack and heap costs [?]. We have developed new theoretical cost models for recursive function definitions, and used these to derive an analysis capable of determining stack and heap costs for recursive Hume programs. This analysis is being validated for soundness against our operational semantics.

We have also constructed a prototype Hume abstract machine (the *pharm*), with an associated abstract machine compiler and runtime implementation, including some runtime profiling information. The Hume abstract machine implementation runs on a number of systems including the Real-Time operating system RT-Linux. It provides guaranteed hard space bounds for the FSM-Hume subset of Hume [?], and has vastly superior time performance to embedded Java implementations.

We have developed a diagrammer for Hume programs, which is written in Java for portability, and which is being extended to a full integrated development environment (IDE).

Finally, we are developing a number of ~~embeddable~~ new realistic control and embedded applications to demonstrate the use of Hume.

The reference interpreter and abstract machine implementation have been developed in tandem and cover the key points of the language design, including all expression forms, coordination, exceptions, timeouts. At present, however, not all types are supported (notable exclusions are unicode characters, fixed-precision and exact arithmetic); type views have not been defined, and we are still clarifying issues related to interrupt handling and low-level I/O.

Our next priorities are to refine our cost models and analyses, to extend our work to cover time as well as space, and to consider machine code implementations.

1.4.2 Foundations for Bounded Space/Time Behaviour

The Hume design builds on foundational research in cost modelling newly developed at St Andrews University. We have developed new theoretical models that...

1.5 Related Work

1.5.1 Embedded Systems

Real-time embedded systems are typically programmed using low-level languages and techniques. Some high level languages have, however, been designed or adapted for such use.

Ada is widely used for embedded systems, and many tools have been constructed to assist the understanding of space and time behaviour [3]. Compared with ANSI standard Ada, Hume provides much higher level of abstraction with a far more rigorously defined semantics, which is specifically designed to support cost semantics.

There has been recent interest in using variants of Java as the basis for embedded systems, though to our knowledge there is as yet no specifically safety-critical design. Two interesting variants are Embedded Java [56] and RTJava [7], for soft real-time applications. Like Hume, both lan-

C.6 Dynamic Semantics: Matches

For clarity, we use a different kind of turnstile (\models) for match inference rules. $E, v \models e \Rightarrow v'$ defines the meaning of *match* with respect to a single matched value e . The semantics for definitions and applications ensures that matches are carried appropriately.

The semantics for pattern-matching is derived from that presented in the Haskell report for case expressions (where the semantics was defined as a translation into a Haskell kernel). This gives a less direct semantics than that of, e.g., Standard ML.

Rules {129–130} define sequences of matches. The first rule applies when the first match in a sequence succeeds, the second when it fails. Failure of the last match in a sequence is us defined by the specific case below, e.g. in the rule for non-matching constructors (Rule 138). Since Hume requires matches to be complete, this will never occur in practice, however. The rules return a new list of matches, with the matched rule at the end. This new list would be used to ensure fair matching on subsequent uses of the box. Rule (131) is used to ensure that the final rule in a sequence is returned if it matches, and to avoid tedious repetition in the individual cases.

$E, v \models \text{matches} \Rightarrow v / FAIL, \text{match}$

$E, v \models \{ \text{match} \} \Leftrightarrow v', \{\text{matches}\}$

$E, v \models \{ \text{match} \mid \text{matches} \} \Rightarrow v', \{ \text{matches} \mid \text{match} \}$

$E, v \models \{ \text{match} \} \Rightarrow FAIL \quad E, v \models \{ \text{matches} \} \Leftrightarrow v, \{ \text{matches}' \}$

$E, v \models \{ \text{match} \mid \text{matches} \} \Rightarrow v, \{ \text{match} \mid \text{matches}' \}$

$E, v \models \{ \text{match} \} \Rightarrow v', \{ \text{match} \}$

$E, v \models \text{match} \Rightarrow v / FAIL$

$\forall i. 0 < i \leq m_i \quad \text{var}_i \notin \bigcup_{j=1}^n F(\text{pat}_{ij} \cup F(\text{exp}_j))$

$E, v \models \left\{ \begin{array}{l} (\text{var}_1, \dots, \text{var}_n) \rightarrow \\ \text{case } (\text{var}_1, \dots, \text{var}_n) \text{ of} \\ \quad \{ (\text{pat}_1, \dots, \text{pat}_n) \rightarrow \text{exp}_1 \\ \quad | \dots \\ \quad | (\text{pat}_m, \dots, \text{pat}_m) \rightarrow \text{exp}_m \} \end{array} \right\} \Rightarrow v'$

$E, v \models \{ \text{pat}_1 \dots \text{pat}_n \rightarrow \text{exp}_1 \dots \text{pat}_m \rightarrow \text{exp}_m \} \Rightarrow v' \quad m \geq 1, n \geq 2$

{132}

The final expression rules are used in constructing matches for case-expressions and function applications. If the expression to be matched is an exception, then the result of the match is an exception; otherwise the matching rules defined below are used. Since fair matching is never used for case-expressions, the reordered match list is discarded.

$$\boxed{E, v \vdash \text{match} \Rightarrow v}$$

$$\frac{\vdash v \Rightarrow v'}{\boxed{E, v \vdash \text{match} \Rightarrow v'}} \quad v' \in \text{Exn} \quad (127)$$

$$\frac{\vdash v \Rightarrow \{\} \quad E, v \vdash \text{match} \Rightarrow v', \text{match}'}{\boxed{E, v \vdash \text{match} \Rightarrow v'}} \quad (128)$$

languages support dynamic memory allocation with automatic garbage collection and provide strong exception handling mechanism. The primary differences from Hume are the omission of arbitrary recursion, an absence of formal design principles, the use of a single-layered approach in which coordination is merged with computation, and of course the use of an object-oriented expression language rather than one that is purely functional. We believe that the design choices made here are more suitable for applications where safety or correctness are important. For example, the use of purely functional rather than dynamically-linked object-oriented design allows straightforward static reasoning about the meaning of programs, at the cost of convenience in modifying a running system.

1.5.2 Real-Time Safety-Critical Systems

Typically, a formal approach to designing safety-critical systems progresses rigorously from requirements specification to systems prototyping. Languages and notations for specification/prototyping provide good formalisms and proof support, but are often weak on essential support for programming abstractions, such as data structures and recursion. Implementation therefore usually proceeds less formally, or more tediously, using conventional languages and techniques. Hume is intended to simplify this process by allowing more direct implementation of the abstractions provided by formal specification languages. Alternatively, in a less formal development process, it can be used to give a higher-level, more intuitive implementation of a real-time problem.

Specification Languages. Safety-critical systems have strong time-based correctness requirements, which can be expressed formally as properties of *safety*, *finiteness* and *timeliness* [7]. Formal requirements specifications are expressed using notations such as temporal logics (e.g. XCTL [16] or MTL [27]), non-temporal logics (e.g. RCTL [23]), or timed process algebras (e.g. LOTOS-T [39], Timed CCS [61] or Timed CSP [50]). Such notations are deliberately non-deterministic in order to allow alternative implementations, and may similarly leave some or all timing issues unspecified. It is essential to crystallise these factors amongst others when producing a working implementation.

Non-Determinism. Although non-determinism may be required in specification languages such as LOTOS [20], it is usually undesirable in implementation languages such as Hume, where predictable and repeatable behaviour is required [7]. Hume thus incorporates deterministic processes, but with the option of fair choice to allow the definition of alternative acceptable outcomes. Because of the emphasis on hard real-time, it is not possible to use the event synchronising approach based on *delaged timestamps* which has been adopted by e.g. the concurrent functional language BRISK [17]. The advantage of the BRISK approach is in ensuring strong determinism without requiring explicit specifications of time constraints as in Hume.

Synchronicity. Synchronous languages such as Signal [5], Lustre [10], Pesto [8, 6] or the visual formalism Statecharts [15] obey the *synchrony hypothesis*: they assume that all events occur instantaneously, with no passage of time between the occurrence of consecutive events [4]. In contrast, asynchronous languages, such as the extended finite state machine languages Estelle [21] and SDL [22], make no such assumption. Hume uses an asynchronous approach, for reasons of both expressiveness and realism. Like Estelle and SDL, it also employs an asynchronous model of communication and supports asynchronous execution of concurrent processes.

Persistency. In order to ensure essential progress even in the absence of some inputs, Hume is deliberately *non-persistent* [7]: the passage of time can force a timeout on an input channel, which can thus influence the choice made by a process. It is also possible for a timeout on an internal computation to have the same effect, although in this case no input will have been consumed. Determinacy is maintained through a strong formal cost model integrated with a formal dynamic

semantics which collectively fully prescribe the outcome of a process instance given the inputs that have been provided.

Dynamic Process Networks. The initial Hume design uses a static process network, as with Petri net approaches, but unlike recent innovations such as π -calculus [40]. This simplifies the formal language semantics, and very importantly, allows the total cost to be specified for the active process network, but does prevent the direct definition of e.g. mobile processes. We do anticipate that some forms of dynamic process could be supported without destroying our overall cost semantics, but have not yet explored this issue.

Summary Comparison. As a vehicle for implementing safety-critical or hard real-time problems, Hume thus has advantages over widely-used existing language designs. Compared with Estelle or SDL, for example, it is formally defined, deterministic, and provably bounded in both space and time. These factors lead to a better match with formal requirements specifications and enhance confidence in the correctness of Hume programs. Hume has the advantage over Lustre and Estelle of providing asynchronicity, which is required for distributed systems. Finally, it has the advantage over LOTOS or other process algebras of being designed as an implementation rather than specification language: *inter alia* it supports normal program and data structuring constructs, allowing a rich programming environment.

1.5.3 Other Models Enforcing Bounded Time/Space Properties

Other than our own work, we are aware of three main studies of formally bounded time and space behaviour in a functional setting [9, 19, 69].

Embedded ML. In their recent proposal for Embedded ML, Hughes and Pareto [19] have combined the earlier *sized type system* [18] with the notion of *region types* [57] to give bounded space and termination for a first-order strict functional language [19]. Their language is more restricted than Hume in a number of ways: most notably in not supporting higher-order functions, and in requiring programmer-specified memory usage.

Inductive Cases. Burstall[9] proposed the use of an extended *ind case* notation in a functional context, to define inductive cases from inductively defined data types. Here, induction is introduced to constrain recursion to always act on a component of the “argument” to the *ind case*, i.e. a component of the data type pattern on which a match is made. While *ind case* enables static confirmation of termination, Burstall’s examples suggest that considerable ingenuity is required to restrict terminating functions based on a laxer syntax.

Elementary Strong Functional Programming. Turner’s *elementary strong functional programming* [60] has similarly explored issues of guaranteed termination in a purely functional programming language. Turner’s approach separates finite data structures such as tuples from potentially infinite structures such as streams. This allows the definition of functions that are guaranteed to be primitive recursive. In contrast with the Hume expression layer, it is necessary to identify functions that may be more generally recursive. We will draw on Turner’s experiences in developing our termination analysis.

Other Related Work. Recent research by Kanureddine and Monin has formalised automatic proofs of termination of recursive functions, by augmenting proof trees with measures that establish an appropriate decreasing property [24]. They have also investigated widening the scope of automatic termination proof from inductive to non-inductive cases [25].

The next expression rules define the semantics of bracketed expressions in terms of the enclosed expression. Profiling and verification expressions are evaluated purely for their effect, and brackets are ignored, as usual).

$$\begin{array}{c}
 \frac{\vdash E \vdash \text{exp} \Rightarrow v}{\vdash E \vdash \text{profile exp}) \Rightarrow v} \quad (118) \\
 \frac{}{\vdash E \vdash \text{exp} \Rightarrow v} \quad (119) \\
 \frac{}{\vdash E \vdash \text{exp} \Rightarrow v} \quad (120) \\
 \frac{}{\vdash E \vdash \text{exp} \Rightarrow v} \quad (121) \\
 \frac{}{\vdash E \vdash \text{exp} \Rightarrow v} \quad (122) \\
 \frac{\vdash \{ v_1, \dots, v_{n-1} \} \Rightarrow v'}{\vdash \{ v_1, \dots, v_{n-1} \} \Rightarrow v' \quad v_n \notin \text{Exn}} \quad (123) \\
 \frac{\vdash \{ v_1, \dots, v_n \} \Rightarrow v' \quad v_n \notin \text{Exn}}{\vdash \{ \} \Rightarrow v' \quad v \in \text{BusVal}} \quad (124) \\
 \frac{}{\vdash \{ \} \Rightarrow \{ \}} \quad (125)
 \end{array}$$

Type signatures have no dynamic component.

$$\frac{E \vdash \exp : type \Rightarrow v}{E \vdash \exp :: type \Rightarrow v} \quad (111)$$

The semantics of type coercion is defined in terms of an auxiliary *coerce* function that implements the semantics of coercion as defined in Section 2.1.3. This function is not specified here.

$$\frac{E \vdash \exp' : type \quad \text{coerce}(v, \text{type}) = v'}{E \vdash \exp' \Rightarrow v' \quad \text{coerce}(v, \text{type}) \Rightarrow v'} \quad (112)$$

Raising an exception simply involves returning it as the value of the expression.

$$\frac{E \vdash \exp : type \Rightarrow v}{E \vdash \text{raisee } \exp \Rightarrow (\text{exnid}, v)} \quad (113)$$

The next set of rules define the semantics of constrained expressions. If the cost of evaluating the expression (as given by the cost function) is greater than the specified constant value, then the corresponding exception is raised, otherwise the value of the within-expression is the same as the encapsulated expression.

$$\frac{\begin{array}{c} E \vdash \exp_2 \Rightarrow t \quad E \vdash \exp_3 \Rightarrow h \quad E \vdash \exp_4 \Rightarrow s \\ \text{timecost}(E, \exp_1) < t \quad \text{heapcost}(E, \exp_1) < h \quad \text{stackcost}(E, \exp_1) < s \end{array}}{E \vdash \exp_1 \text{ within } \exp_2, \exp_3(\exp_4) \mid \text{raise exnid} \Rightarrow v} \quad (114)$$

$$\frac{\begin{array}{c} E \vdash \exp_2 \Rightarrow t \quad E \vdash \exp_3 \Rightarrow h \\ \text{timecost}(E, \exp_1) \geq t \end{array}}{E \vdash \exp_1 \text{ within } \exp_2, \exp_3(\exp_4) \mid \text{raise exnid} \Rightarrow (\text{exnid}/\text{Timeout}, \{ \ })} \quad (115)$$

$$\frac{\begin{array}{c} E \vdash \exp_2 \Rightarrow t \quad E \vdash \exp_3 \Rightarrow h \\ \text{timecost}(E, \exp_1) < t \quad \text{heapcost}(E, \exp_1) \geq h \\ E \vdash \exp_1 \text{ within } \exp_2, \exp_3(\exp_4) \mid \text{raise exnid} \Rightarrow (\text{exnid}/\text{HeapOverflow}, \{ \ }) \end{array}}{E \vdash \exp_1 \text{ within } \exp_2, \exp_3(\exp_4) \mid \text{raise exnid} \Rightarrow (\text{exnid}/\text{StackOverflow}, \{ \ })} \quad (116)$$

$$\frac{\begin{array}{c} E \vdash \exp_2 \Rightarrow t \quad E \vdash \exp_3 \Rightarrow h \quad E \vdash \exp_4 \Rightarrow s \\ \text{timecost}(E, \exp_1) < t \quad \text{heapcost}(E, \exp_1) < h \quad \text{stackcost}(E, \exp_1) \geq s \\ E \vdash \exp_1 \text{ within } \exp_2, \exp_3(\exp_4) \mid \text{raise exnid} \Rightarrow (\text{exnid}/\text{StackOverflow}, \{ \ }) \end{array}}{E \vdash \exp_1 \text{ within } \exp_2, \exp_3(\exp_4) \mid \text{raise exnid} \Rightarrow (\text{exnid}/\text{StackOverflow}, \{ \ })} \quad (117)$$

Also relevant to the problem of bounding time costs is recent work on *cost calculus* [51, 53] and *cost modelling* [49, 31, 54], which has so far been primarily applied to parallel computing.

1.6 Papers and Documentation

Research papers on Hume, implementations and documentation can all be found at the Hume web page <http://www.cs.st-and.ac.uk/hume>.

1.7 Changes from Version 1.0

The main changes introduced in version 1.1 of the report are:

- vectors are now specified with a size rather than a bound;
- strings were never a synonym for `char`;
- corrections to the basic operations;
- corrections to the syntax.

1.8 Changes from Version 0.2

The main changes introduced in version 1.0 of the report are:

- added interrupt, fifo, memory and operation;
- added foreign function interfacing and operation;
- added profile and verify expressions;
- added descriptions of declarations;
- extended within expressions to space as well as time;
- included timeouts on I/O descriptors;
- removed port, stream and bandwidth types.

In addition, a number of issues were clarified, errors corrected, and obsolete design decisions eliminated.

$$\frac{\begin{array}{c} E \vdash \exp_2 \Rightarrow t \quad E \vdash \exp_3 \Rightarrow h \\ \text{timecost}(E, \exp_1) < t \quad \text{heapcost}(E, \exp_1) \geq h \\ E \vdash \exp_1 \text{ within } \exp_2, \exp_3(\exp_4) \mid \text{raise exnid} \Rightarrow (\text{exnid}/\text{HeapOverflow}, \{ \ }) \end{array}}{E \vdash \exp_1 \text{ within } \exp_2, \exp_3(\exp_4) \mid \text{raise exnid} \Rightarrow (\text{exnid}/\text{StackOverflow}, \{ \ })} \quad (116)$$

Chapter 2

Hume Overview

This chapter introduces the Hume language. Section 2.1 describes the set of fundamental types that are supported by the language, together with the operations that are provided on those types. These types are intended to form a fairly minimal set, allowing the construction of realistic programs without requiring complex implementation in the initial stages. In the longer term, we expect to support a richer set of types in later versions of Hume.

One important concern for any such language is the matter of type coercion and conversion, especially between scalar values. Hume therefore provides a wide range of scalar types, and defines precisely the conversions between values of those types. Hume scalar types include booleans, characters (including unicode), variable sized word values, fixed-precision integers (including natural numbers), floating-point values, fixed-exponent real numbers, and exact real numbers.

A second, related concern is the need to specify the sizes of such values. Hume meets this concern by requiring the size of all scalar values to be specified precisely.

In addition to scalar types, Hume supports three kinds of structured type: vectors, lists and tuples. Vector and tuple types are fixed size, whereas lists may be arbitrary sized. All the elements of a single vector or list must have the same type.

2.1 Types

2.1.1 Base Types

All Hume type domains are unpointed [12]. That is, there is no explicit notion of an *undefined* value (\perp) in each type domain. The Hume *base types* are shown in Table 2.1. The type `bit` is a synonym for word 1, and the type `byte` is a synonym for word 8.

The basic operations provided for each type are shown in Table 2.2. The integer division and remainder operators (`mod`) have the property that $a \text{ div } b * b + (a \text{ mod } b)$. The result of $x \text{ div } y$ has the same sign as $x * y$ and is truncated towards zero. The value of $x ** 0$ is 1 for any x , including zero. For word, `&`, `|`, `^` are bitwise and, inclusive or, exclusive or, and negation respectively. The `lshl` and `lshr` operations pad to left/right with 0s respectively, as required.

2.1.2 Structured types

The Hume structured types are shown in Table 2.3, with the corresponding operations shown in Table 2.4. Streams and ports may only be associated with boxes — see below.

⁷The next set of rules define the semantics for primitive constructors, including lists, tuples and vectors. The semantics of non-empty lists is given in terms of that for the constructors `(:)` and `Nil`, while that for non-empty vectors is given in terms of that for tuples.

$\frac{}{\mathcal{E} \vdash (\:) \exp_1 \{ \dots ((\:) \exp_n \{ \dots \}) \Rightarrow v} \quad (102)$	$\frac{}{\mathcal{E} \vdash [\exp_1, \dots, \exp_n] \Rightarrow v} \quad n \geq 1 \quad (103)$	$\frac{}{\mathcal{E} \vdash (\:) \Rightarrow \text{Nil} \{ \}} \quad (104)$
<hr/>	<hr/>	<hr/>
$\frac{}{\mathcal{E} \vdash (\:) \Rightarrow (\:)} \quad (105)$	$\frac{\forall i. \ 1 < i \leq n, \ \mathcal{E} \vdash \exp_i \Rightarrow v_i \quad \vdash \{v_1, \dots, v_n\} \Rightarrow v' \quad v' \notin \text{Exn}}{\mathcal{E} \vdash (\exp_1, \dots, \exp_n) \Rightarrow (\: v_1, \dots, v_n)} \quad (106)$	$\frac{\forall i. \ 1 < i \leq n, \ \mathcal{E} \vdash \exp_i \Rightarrow v_i \quad \vdash \{v_1, \dots, v_n\} \Rightarrow v' \quad v' \in \text{Exn}}{\mathcal{E} \vdash (\exp_1, \dots, \exp_n) \Rightarrow v'} \quad (107)$
<hr/>	<hr/>	<hr/>
$\frac{}{\mathcal{E} \vdash (\exp_1, \dots, \exp_n) \Rightarrow v} \quad (108)$	$\frac{\mathcal{E} \vdash (\exp_1, \dots, \exp_n) \Rightarrow v}{\mathcal{E} \vdash (\exp_1, \dots, \exp_n) >> \{v_1, \dots, v_n\}} \quad (109)$	$\frac{\mathcal{E} \vdash (\exp_1, \dots, \exp_n) \Rightarrow v}{\mathcal{E} \vdash \text{case exp of match } \Rightarrow v} \quad (110)$
<hr/>	<hr/>	<hr/>

The semantics of case-expressions is defined by matching the value of the expression against the match. Note that the semantics for conditional expressions (rule 109) is defined in terms of the semantics for case-expressions (rule 108).

Let-expressions have a simple semantics.

C.5 Dynamic Semantics: Expressions

$$E \vdash \exp \Rightarrow v$$

The first few rules handle the semantics for simple expressions, including variables, basic values, nullary constructors, characters, and strings.

$$E \vdash (var) \Leftarrow v \quad (94)$$

$$E \vdash \text{var} \Rightarrow v \quad (94)$$

$$E_0 \vdash b = \exp \quad E \vdash \exp \Rightarrow v \quad (95)$$

$$E \vdash b \Rightarrow v \quad (95)$$

$$E \vdash \text{con} \Rightarrow \text{con} \langle \rangle \quad (96)$$

$$E \vdash \text{char} \Rightarrow \text{char} \quad (97)$$

$$\text{suul}(\text{string}) \Leftarrow v \quad (98)$$

$$E \vdash \text{string} \Rightarrow v \quad (98)$$

The next rule defines the semantics of function applications as the application of the body of the function to a tuple of the arguments. There is no semantics of partial application.

$$E \vdash (\text{var}) \Leftarrow \text{matches} \quad \forall i. 1 < i \leq n. E \vdash \exp_i \Rightarrow v_i \quad E_i(v_1, \dots, v_n) \vdash \text{matches} \Rightarrow v^* \quad (99)$$

$$E \vdash \text{var} \exp_1 \dots \exp_n \Rightarrow v^* \quad (99)$$

$$E \vdash (\exp_1, \dots, \exp_n) \Rightarrow v \quad v \notin \text{Exn} \quad (100)$$

$$E \vdash \text{con} \exp_1 \dots \exp_n \Rightarrow \text{con} v \quad (101)$$

$$E \vdash (\exp_1, \dots, \exp_n) \Rightarrow v \quad v \in \text{Exn} \quad (101)$$

$$E \vdash \text{con} \exp_1 \dots \exp_n \Rightarrow v \quad (101)$$

bool	boolean i.e. true : false
char	8 bit - ISO Latin-1 denoted by: 'printable'
unicode	16 bit Unicode
word <precision>	bits of specified size, in the range 0... $2^n - 1$
int <precision>	2's complement integer of specified bit size,
nat <precision>	in the range $-2^{n-1} \dots 2^n - 1$
float <precision>	natural number i.e. ≥ 0 of specified bit size,
fixed <precision>	in the range 0... $2^n - 1$
fixed <precision> [\oplus (2 10 16) [* * <exponent>]]	floating point number of specified bit size (IEEE representation)
exact	fixed exponent real of specified bit size, and optional base / exponent
	exact real number

Table 2.1: Hume base types

bool	$\text{Eq} \sqsubseteq \text{I}$

Table 2.4: Basic Operations on Structured types

$E \vdash P \Rightarrow v, E, E$	$W(\text{boxid}) = \langle \text{wins}, \text{wouts} \rangle$ $n = \text{wins} $ $SE \approx SE \text{ of } E$ $vs = \langle \text{snif}(SE(\text{wins}_1)), \dots, \text{snif}(SE(\text{wins}_n)) \rangle$ $SE^I = \{ \forall i. 1 \leq i \leq n, \text{wins}_i \mapsto \langle \text{import wins}, \mu \text{ vs}_i \rangle \}$ $SE^Q = \{ \forall i. 1 \leq i \leq \text{wouts} , \text{wouts}_i \mapsto \langle \text{true}, [\text{vs}_i] \rangle \}$ $E, W \vdash \langle \text{boxid}, \text{ins}, \text{outs}, \text{body} \rangle \Rightarrow \text{vs}', SE', SE''$	(90)
		<p>E, vs \vdash body \Rightarrow vs'</p> <p>\vdash ...</p>
		$E, v \vdash \text{body} \Rightarrow v$
$E \vdash \text{time} \Rightarrow t$ $\vdash E, v \Rightarrow \text{timeout time matches handle handles}$	$timecost(E, \text{matches}(\text{vs})) < t$ $E, \text{vs} \vdash \text{matches} \Rightarrow v, \text{matches}$ $E, v \vdash \text{handle} \Rightarrow v, \text{matches}$	(91)
$E \vdash \text{time} \Rightarrow t$ $E, \text{vs} \vdash \text{timeout time matches handle handles} \Rightarrow v'$	$timecost(E, \text{matches}(\text{vs})) \geq t$ $E, \text{vs} \vdash \text{handles} \Rightarrow v, \text{matches}$	(92)
		$v \in \text{Rxn}$

The final set of process rules define the semantics of executing a single box body. There are three cases, corresponding to normal execution, an exception or a timeout respectively. In order to implement fair matching, the new rule ordering returned by the match rule should update the definition of the matches for the box in the environment. In this way, each successful fair match will change the rule ordering, thereby ensuring that each rule is matched equally, as required by the semantics.

Processes are split into active/inactive sets, and all active processes are scheduled for one step, yielding a new environment.

$$\boxed{E, W \vdash P \Rightarrow E}$$

$$\frac{E, W \vdash I, A \Rightarrow E, Y, A' \quad E', W \vdash I, A' \Rightarrow E'}{E, W \vdash I, A \Rightarrow E', Y, A'} \quad (86)$$

$$\frac{E, W \vdash P \Rightarrow I, A \quad E, W \vdash I, A \Rightarrow E'}{E, W \vdash P \Rightarrow E'} \quad (86)$$

Processes are scheduled repeatedly until the set of active processes becomes empty.

$$\boxed{E, W \vdash P, P \Rightarrow E}$$

$$\frac{E, W \vdash I, A \Rightarrow E, Y, A' \quad E', W \vdash I, A' \Rightarrow E'}{E, W \vdash I, A \Rightarrow E', Y, A'} \quad (87)$$

When there are no further active processes, the program terminates.

$$\boxed{E, W \vdash I, \{ \} \Rightarrow E} \quad (88)$$

Each active process is executed for one step and the output redirected to the input specified in the wiring specification. All processes are then reassessed to determine their new activity status.

$$\boxed{E, W \vdash P, P \Rightarrow E, P, P}$$

$$\forall i. 1 \leq i \leq |A|, E, W \vdash A_i \Rightarrow \text{outsc}_i E_i^I, E_i^O$$

$$E^I = \bigcup_{i=1}^{|A|} E_i^I \oplus \bigcup_{i=1}^{|A|} E_i^O$$

$$\frac{E \stackrel{\leftrightarrow}{\oplus} E', W \vdash I \cup A \Rightarrow I', A' \quad E, W \vdash I, A \Rightarrow (E \oplus E'), I, A'}{E, W \vdash I, A \Rightarrow (E \oplus E'), I, A'} \quad (89)$$

Table 2.5: Conformance between Hume base types.

	bool	int	nat	float	fixed	exact	char	unicode	word
bool	Y(1)	Y	Y	Y	Y	Y	Y	Y	Y
int	Y(1)	Y(6)	Y(2)	Y	Y	Y	Y	Y(5)	Y(5)
nat	Y(1)	Y(5)	Y(6)	Y	Y	Y	Y	Y(4)	Y(4)
float	Y(7)	Y(8)	Y(7)	Y	Y	Y	Y	Y(5)	Y(5)
fixed	Y(1)	Y(7)	Y(8)	Y(7)	Y	Y	Y	Y(5)	Y(5)
exact	Y(1)	Y(9)	Y(9)	Y(9)	Y(9)	Y	Y	Y(5)	Y(5)
char	Y	Y	Y	Y	Y	Y	Y	Y	Y
unicode	Y	Y(5)	Y(5)	Y(5)	Y(5)	Y	Y	Y	Y
word	Y	Y(5)	Y(5)	Y(5)	Y(5)	Y(5)	Y	Y	Y

Notes

1. int \approx 0 or int \approx 1
2. int \geq 0
3. 0 \ll int \ll 256
4. 0 \ll int \ll 2^{31-1}
5. 0 \ll int \ll $2^{32-word precision-1}$
6. nat precision \ll int precision
7. trunc, round, ceiling
8. float > 0 and as int
9. subject to further discussion...

2.1.3 Type Conversions

There are two kinds of type conversion. Casting (or viewing) involves treating a value as if it belonged to another equivalent type. One type may be cast to another using `<expr> :: <type>`, if there is no loss of information when converting from a value of the type of `<expr>` to `<type>`, and if the conversion can be done with no runtime cost.

The second form of type conversion is coercion. In this case, there may be loss of information and there may also be a runtime cost. The corresponding form is `<expr> as <type>`. The conformance between base types is as shown in Table 2.5. The most significant bit in a word is to the left. Base values are right aligned and left padded.

Coerced structured types:

- must have the same number of elements at all levels
- are aligned top down, recursively, element by element left to right

2.1.4 Exceptions

Exceptions are:

- declared by: exception `<id> <type>`, within declarations (Section 2.2);
- raised by: raise `<id> <expr>` within expressions (Section 2.3.9);
- handled by: handle `<handlers>` within boxes (Section 2.4.3).

System exceptions may be handled either within a box or by a general system handler. If a box defines a handler for a system exception, and the exception is raised as a consequence of executing

that box, then the specified handler is called. If a box fails to define a handler for a system exception and that system exception occurs during the process of executing the box, then the general system handler is called. There must be precisely one general handler for each system exception. The system exceptions are:

Div0	division by 0
Overflow/Underflow	numeric overflow/underflow
OutOfBounds	out of bounds vector index
HeapOverflow	heap overflow
StackOverflow	stack overflow
Timeout	timeout
EndOfFile	end of input file

Note that `HeapOverflow` and `StackOverflow` are only raised by code whose heap/stack costs have not been certified, and then in the context of a within-constraint on boxes or expressions. `Timeout`s occur through within/timeout constraints on ports, streams, wires, boxes or expressions.

2.2 The Declaration Layer

The declaration layer introduces types and values that scope over either or both the coordination and expression layers. The coordination layer is embedded in terms of box and wiring declarations while the expression layer is embedded in terms of function declarations.

While it is possible to define recursive and mutually recursive functions, it is not possible to do the same for simple values.

2.2.1 Function, Value and Constant Declarations

Functions and named values are introduced in a similar way to their Haskell counterparts. Values may be declared to be `constant`, in which case their value is calculated at compile-time. Such constant values must be simple calculations and may not be defined using function calls, within constraints etc. Named constants may be used in the writing mismatchchange, in expression macros, or in any other place where a constant expression is mandated. The form `varid :: <type>` indicates only that the variable has the specified type, and must be accompanied by a value or function declaration. It is not an error to omit a type declaration, however, in this case, the variable or function is assigned the most general type possible by the compiler using a standard Dumas-Milner type inference algorithm [7].

```
<dec1> ::= ...
| <fundec1>
| "constant" <varid> "n" <expr>
<fundec1> ::= ...
| <varid> ":" <type>
| <varid> <args> "n" <expr>
| <patt1> <op> <patt2> "n" <expr>
<args> ::= ...
<patt1> ... <pattn> n >= 0
```

For example, we can define the ubiquitous `nfib` function as follows:

The set of processes is split into active (A) and inactive processes (I). A process is active if input is available on all its input channels, or if a timeout has been raised on any input channel.

$$\boxed{E, W \vdash P \Rightarrow P, P}$$

$$\frac{\text{Vi. } 1 \leq i \leq n, E, W \vdash P_i \Rightarrow I_i, A_i}{E, W \vdash \{ P_1, \dots, P_n \} \Rightarrow I, A} \quad (81)$$

$$\frac{\text{Vi. } 1 \leq i \leq n, E, W \vdash P_i \Rightarrow I_i, A_i \quad \bigcup_{i=1}^n I_i = A}{E, W \vdash P \Rightarrow P, P} \quad (82)$$

Rules 82–85 determine whether individual inputs are available or have timed out.

$$\boxed{E, W \vdash P \Rightarrow P, P}$$

$$\frac{\text{P} = \langle \text{boxid}, \text{ins}, \text{outs}, \text{body} \rangle \quad W(\text{boxid}) = \langle \text{wins}, \text{wouts} \rangle}{E \vdash \text{wins} \Rightarrow b, b'} \quad I, A = \text{if } b \vee b' \text{ then } \{ I, \{ P \} \} \text{ else } \{ I, \{ \} \} \quad (83)$$

$$\frac{E, W \vdash P \Rightarrow I, A}{E, W \vdash P \Rightarrow I, A'} \quad (84)$$

$$\boxed{E \vdash \text{id}s \Rightarrow \text{bool}, \text{bool}}$$

$$\frac{E \vdash \text{id}_1 \Rightarrow \text{true}, b \quad E \vdash \text{id}_2 \dots \text{id}_n \Rightarrow b', b''}{E \vdash \text{id}_1 \dots \text{id}_n \Rightarrow b', (b \vee b'')} \quad (83)$$

$$\frac{E \vdash \text{id}_1 \Rightarrow \text{false}, b \quad E \vdash \text{id}_2 \dots \text{id}_n \Rightarrow b', b''}{E \vdash \text{id}_1 \dots \text{id}_n \Rightarrow \text{false}, (b \vee b'')} \quad (84)$$

$$\boxed{E \vdash \text{id} \Rightarrow \text{bool}, \text{bool}}$$

$$\frac{E(\text{id}) = \{ b, \text{vs} \} \quad b' = \text{if } \text{vs} = \emptyset \text{ v } \text{hd vs} \neq (\text{Timeout}, \{ \}) \text{ then } \text{false} \text{ else } \text{true}}{E \vdash \text{id} \Rightarrow b, b'} \quad (85)$$

C.4 Dynamic Semantics: Processes

```
nfib : int 32 -> int 32;
nfib 0 = 1;
nfib n = 1 + nfib(n-1) + nfib (n-2);
```

The dynamic semantics of a Hume program is given by the dynamic semantics of the boxes that are defined in the program. This semantics is produced in the context of the declarations and wirings that are specified in that program plus the initial environment of prelude bindings and imported values. The result of a Hume program is a new environment reflecting the state of new bindings in the system or value environments.

$\boxed{\text{SE}, \text{IE} \vdash \text{program} \Rightarrow \text{E}}$

$$\frac{\begin{array}{c} \text{E}_0 \oplus \text{IE} \vdash \text{decls} \Rightarrow \text{E} \\ \vdash \text{boxes} \Rightarrow \text{P} \\ \vdash \text{wires} \Rightarrow \text{W} \\ ((\text{B}_0 \oplus \text{E}) \oplus \text{IE} \oplus \text{SE}), \text{W} \vdash \text{P} \Rightarrow \text{E}' \end{array}}{\text{SE}, \text{IE} \vdash \text{program decls boxes wires} \Rightarrow \text{E}'} \quad (76)$$

Box declarations are processed to give a set of initial processes, P.

$\boxed{\vdash \text{boxes} \Rightarrow \text{P}}$

$$\frac{\begin{array}{c} \forall i, 1 < i \leq n, \vdash \text{box}_i \Rightarrow \text{P}_i \\ \vdash \text{box}_1 \dots \text{box}_n \Rightarrow \bigcup_{i=1}^n \text{P}_i \end{array}}{\vdash \text{box} \Rightarrow \text{P}} \quad (77)$$

$\boxed{\vdash \text{box} \Rightarrow \text{P}}$

$$\frac{\vdash \text{box} \text{ boxid ins outs body} \Rightarrow \{ (\text{boxid}, \text{ins}, \text{outs}, \text{body}) \}}{\vdash \text{box} \Rightarrow \text{W}} \quad (78)$$

wiring declarations are processed to give the wiring layout mapping the outputs of boxes or I/O operations to the inputs of other boxes.

$\boxed{\vdash \text{wires} \Rightarrow \text{W}}$

$$\frac{\begin{array}{c} \forall i, 1 < i \leq n, \vdash \text{wire}_i \Rightarrow \text{W}_i \\ \vdash \text{wire}_1 \dots \text{wire}_n \Rightarrow \bigcup_{i=1}^n \text{W}_i \end{array}}{\vdash \text{wires} \Rightarrow \text{W}} \quad (79)$$

$\boxed{\vdash \text{wire} \Rightarrow \text{W}}$

$$\frac{\begin{array}{c} \text{W} = \{ \text{boxid} \mapsto \{ \text{sources}, \text{dests} \} \} \\ \vdash \text{wire boxid sources dests} \Rightarrow \text{W} \end{array}}{\vdash \text{wire boxid sources dests} \Rightarrow \text{W}} \quad (80)$$

```
nfib : int 32 -> int 32;
```

```
nfib 0 = 1;
```

```
nfib n = 1 + nfib(n-1) + nfib (n-2);
```

and we could define a constant `arraylen`, by, e.g. `constant arraylen = 100`.

2.2.2 Type Declarations

Hume includes two kinds of type declaration, both of which are defined analogously to their Haskell counterparts. The first form introduces a new constructed data type whose alternatives are distinguished by different data constructors (a discriminated union type). The second form introduce a *type synonym*: a named type equivalent to some pre-existing type. Either form of declaration may be *polymorphic*, in which case it must be provided with a number of type variable arguments (these may then appear within the type declaration part). Constructed types may also be defined recursively.

$\langle \text{decl} \rangle ::= \dots$
 | "data" <typeid> <varids> "=" <constructs>
 | "type" <typeid> <varids> "" <types>

$\langle \text{constructs} \rangle ::= \dots$
 | <conid1> <type1> ... <type1n> $\text{m} > 0, \text{n} \geq 0$
 | """
 | <conidm> <typem1> ... <typemn>

So, for example, we can define a new type of polymorphic binary trees, and a version that is specialised to 32-bit integers, by:

```
data Tree a = Leaf a | Node (Tree a) (Tree a);
```

```
type IntTree = Tree (int 32);
```

User-defined types (whether data types or type synonyms) may be used wherever pre-defined types may be used, and data constructors may be used both in pattern-matching and in expressions.

2.2.3 Exception Declarations

Hume exceptions are typed. A Hume exception is a constructed value like a data type, which is raised by a `raise` expression or as the result of a system exception, and which is handled by exception handlers introduced at the box level.

$\langle \text{decl} \rangle ::= \dots$
 | "exception" <exnid> ":" <exprtype>

For example, we can define a new exception over a string, with the corresponding `raise` and `handle` clauses as follows:

```
exception X :: string;
box B in ( ... ) out ( res : string )
handles X
```

```

match ... -> ... raise (X "overflow") ...
handle X s -> s;

E ⊢ var matches { var ↦ matches }   (72)

E ⊢ op pat1 pat2 = exp ⇒ E   (73)
E ⊢ pat1 op pat2 ≈ exp ⇒ E
E ⊢ exp ≈ v                         (74)
E ⊢ var :: type ⇒ { }               (75)

```

`<decl>` ::= ...
| "import" <id> <idlist>
| "export" <idlist>

In the import form, `<id>` is the name of the module to be imported.
In both forms, `<idlist>` is the list of entities to be imported or exported.
So, for instance,

```

import M (a,b);
export f;

```

imports `a` and `b` defined in module `M` for use in the current module, and exports `f`.

2.2.4 Import/Export Declarations

Hume import and export declarations respectively introduce identifiers that have been defined in some other module, or expose identifiers from the currently defined module for use elsewhere.

```

<decl> ::= ...
| "import" <id> <idlist>
| "export" <idlist>

```

In the import form, `<id>` is the name of the module to be imported.

In both forms, `<idlist>` is the list of entities to be imported or exported.

So, for instance,

```

import M (a,b);
export f;

```

imports `a` and `b` defined in module `M` for use in the current module, and exports `f`.

2.2.5 Foreign Function Interfacing

Hume uses the same notation for foreign function interfacing as Haskell [?]. This allows reuse of standard interface generator tools such as GreenCard. External calls are specified using foreign function declarations which provide information about the calling convention to be used, whether the function is safe or unsafe, and the Hume type of the function. The optional string is used to provide additional information to the compiler related to the calling language: for C calls, this includes the name of the function if different from the Hume name plus information about files that must be included in the compiled code. Note that it may be necessary to link compiled Hume code with additional libraries or undertake other special actions as specified by the implementation in order to exploit external calls.

Note that it is not permitted to use `unsafe` foreign calls in Hume expressions; they may only be used in Hume operations. The safety clause is retained for backwards compatibility with the Haskell FFI. In this way referential transparency is preserved for Hume expressions even in the presence of foreign function calls.

```

<foreigndecl> ::= "foreign" "import" <callconv> [ <safety> ] [ <string> ] <id> ":" <exprtype>
| "foreign" "export" <callconv> [ <string> ] <id> ":" <exprtype>
<safety> ::= "safe" | "unsafe"
<callconv> ::= "ccall" | "stdcall" | "cplusplus" | "jvm" | "dotnet"

```

Note that in `<foreigndecl>`, `<string>` typically consists of the library name followed by the name of the library entity, and `<id>` is the Hume name for the entity.

C.3 Dynamic Semantics: Declarations

Declarations are processed to generate an initial environment mapping identifiers to initial values. This environment is used in the dynamic semantics for expressions to determine the value of identifiers in function applications and variable expressions (rules 99, 94) and in the semantics of boxes to determine the value attached to an I/O object (rule 90). Declarations may be self-referencing or mutually recursive.

$$\boxed{E \vdash \text{decls} \Rightarrow E}$$

$$\boxed{E \vdash \text{decl}_1 \dots \text{decl}_n \Rightarrow E \oplus \bigoplus_{i=1}^n E_i}$$

$$\boxed{E \vdash \text{import} \text{id} \text{ var}_1 \dots \text{var}_n \Rightarrow \{ \}}$$

Each declaration is processed to produce a corresponding value environment.

$$\boxed{E \vdash \text{decl} \Rightarrow VE}$$

$$\boxed{E \vdash \text{foreign export} \text{id} \text{ str} \text{ var} :: \text{type} \Rightarrow \{ \}}$$

$$\boxed{E \vdash \text{foreign import} \text{id} \text{ str} \text{ var} :: \text{type} \Rightarrow \{ \}}$$

$$\boxed{E \vdash \text{foreign export} \text{id} \text{ str} \text{ var} :: \text{type} \Rightarrow \{ \}}$$

$$\begin{aligned} & E \vdash \text{exp} \Rightarrow v \\ & E \vdash \text{constant id} = \text{exp} \Rightarrow \{ \text{id} \mapsto v \} \\ & (\text{SE of } E) \text{id}' = \text{vs} \\ & E \vdash \text{port}/\text{stream}/\text{memory}/\text{fifo} \text{id from} \text{id}' \Rightarrow \{ \text{id} \mapsto \{ \text{true}, \text{vs} \} \} \end{aligned} \quad (70)$$

$$\begin{aligned} & E \vdash \text{expr} \Rightarrow v \quad (\text{SE of } E) \text{id}' \Rightarrow \text{vs} \quad \text{vs}' = \{ \text{v}, \text{vs} \} \\ & E \vdash \text{port}/\text{stream}/\text{memory}/\text{fifo} \text{id from} \text{id}' \text{ initial expr} \Rightarrow \{ \text{id} \mapsto \{ \text{true}, \text{vs} \} \} \end{aligned} \quad (71)$$

For example, `foreign import ccall "math.h sin" hsin :: float 32 -> float 32` specifies a Hume function `hsin` which is defined as the C function `sin` in the `math.h` header file. Operations extend the foreign function interface, providing a wrapper for (possibly) unsafe foreign function calls. An operation introduces a new box with one input, named `inp`, and one output, named `outp`. The string describes the foreign function us for the optional string in a foreign function import declaration. Only the `ccall` calling convention is supported.

$$\langle \text{decl} \rangle ::= \dots \mid \langle \text{operation} \rangle \langle \text{boxids} \rangle \text{ as} \langle \text{string} \rangle \text{ ":"} \langle \text{type} \rangle$$

For example, `operation System as "system" :: String -> ()` introduces a new box called `System` whose purpose is to execute the `system` function call (on a Unix system, this will cause its argument to be executed as an operating system command, for instance). The call is performed synchronously, returning the unit tuple value `(())` on completion. The `System` box is wired normally, for example,

$$\begin{aligned} & \text{wire b}.systemcall \text{ to } \text{System}.inp; \\ & \text{wire System.outp to b.done}; \end{aligned}$$

wires its input to `b.systemcall` and its output to `b.done`.

2.2.6 Expression Declarations

Where the result of a Hume program is a single expression rather than a set of boxes, then a special shorthand form is available.

$$\langle \text{decl} \rangle ::= \dots \mid \langle \text{expression} \rangle \langle \text{expr} \rangle$$

An expression declaration introduces a box with no input, and whose output is directed to the standard output stream. The box runs precisely once, and may use any defined function or expression form. For example, `expression fib 100` produces the program whose purpose is to calculate $\sqrt{ }$

2.3 The Expression Layer

The Hume expression layer follows the design of widely used functional languages such as Standard ML [41] and Haskell [7]. Like Standard ML, Hume expressions follow a strict evaluation order. This allows tight cost functions to be derived for Hume expressions and allows a relatively simple semantics of exceptions to be specified (see Appendix C). Like Haskell, the Hume expression layer is purely functional. In order to simplify code reuse, the syntax of the Hume expression layer is broadly based on that of Haskell, and is fully described in Appendix A. The formal dynamic semantics of the Hume expression layer is given in Appendix C.

2.3.1 Constants

Constants are simple constant values covering the basic Hume types. Characters are 1-byte ASCII characters conforming to ISO-Latin-1 and have type `char`. Multi-byte characters may be formed using `bytes` constants, and have type `unicode`. So, for example, `'\u222AE'` is the Unicode character representing the mathematical symbol \bot .

$\langle \text{expr} \rangle ::= \dots$	$\langle \text{constant} \rangle$	
$\langle \text{constant} \rangle ::=$		
$\langle \text{intconst} \rangle$		
$\langle \text{floatconst} \rangle$		
$\langle \text{boolconst} \rangle$		
$\langle \text{charconst} \rangle$		
$\langle \text{stringconst} \rangle$		
$\langle \text{wordconst} \rangle$		
$\langle \text{timeconst} \rangle$		
2.3.2 Variables		
Variables are defined either in function declarations, constant declarations, or in pattern matches. In the first two cases, their value is as specified in the corresponding declaration. The value of a constant can be obtained without runtime computation, that of a variable declared in a function declaration may require computation. In the final case, the value of the variable is obtained by deconstructing the matched expression as a consequence of the pattern matching operation. No further computation is required.		
$\langle \text{expr} \rangle ::= \dots$		
$\langle \text{varid} \rangle$		
variable/constant		

2.3.3 Constructors

Constructors are used to build new data structures. They are defined by union declarations to be components of some discriminated union type.

$\langle \text{expr} \rangle ::= \dots$		
$\langle \text{conids} \rangle \langle \text{expr1} \rangle \dots \langle \text{exprn} \rangle$		constructor $\text{appl}_i, n \geq 0$

2.3.4 Tuples, Lists and Vectors

Tuples, lists and vectors are created in a similar way to user-defined constructors, but for convenience, special syntax is provided. It is not possible to create a tuple of one element. An "empty" tuple can be created using the syntax $\langle \rangle$.

$\langle \text{expr} \rangle ::= \dots$		
$"[" \langle \text{expr} \rangle "]"$		list
$"()"$		empty tuple
$"{" \langle \text{expr} \rangle ",", \langle \text{expr} \rangle "}"$		tuple
$"<" \langle \text{expr} \rangle ">"$		vector

$\langle \text{exprs} \rangle ::=$		
$\langle \text{expr} \rangle ",", \dots ",", \langle \text{expr} \rangle$		$n \geq 0$

2.3.5 Function Applications

Hume function applications have a strict semantics. All arguments to a function are evaluated from right-to-left before the function is called. All functions in Hume must be fully applied:

Currying and partial applications are not supported. Higher-order functions are supported, but may have cost implications as discussed in Section ??.

Appendix C

Dynamic Semantics

This appendix defines the Hume dynamic semantics using an axiomatic style. It is divided into five parts: i) overview and definitions; ii) the semantics of declarations; iii) the semantics of processes; iv) the semantics of expressions; and v) the semantics of pattern matches. The semantics assumes that all static checks and translations defined by the static semantics are valid and have been properly carried out.

C.1 Limitations

There are a number of limitations on the semantics given here. Firstly, we do not consider the semantics of imported values. This can be added straightforwardly by extending the initial value environment with bindings for the imported values. Secondly, the semantics of processes assumes that all active processes are scheduled for precisely one step. The status of all processes is then reassessed to determine whether each process is active or inactive. A more flexible semantics would schedule precisely one active process. This modification should not be too hard to incorporate into the semantics. Thirdly, we need to define the semantics of the *timeout*, *slackcast*, *heappost* and *coerce* functions which are used to calculate timeouts and type coercions respectively. We anticipate that the semantics of type coercions can be defined without great difficulty. We are in the process of developing formal analyses for providing upper bound on stack and heap usage for Hume programs, including primitive recursion. We anticipate that it will be possible to extend these analyses to cover time using analytical techniques developed for other real-time languages [?, ?]. Fourthly, we have not defined the semantics for interrupts. Clearly a polling semantics is not ideal for such objects, though they may possess a similar semantics to other kinds of I/O operations? Finally, the dynamic semantics is currently defined only for the asynchronous language (i.e. omitting fair matches and *), and does not consider higher-order functions. We anticipate extending the semantics to cover these constructs in due course.

C.2 Dynamic Semantics: Notation

The dynamic semantics uses a similar style to that used for the static semantics in Appendix B. Our semantics is given in terms of the semantic domain *SemVal* defined below. We use $\{\cdot\}$ to enclose semantic tuples in the *SemVal* domain. This avoids confusion with the syntactic tuple domains, and allows the direct representation of 1-tuples where necessary. The notation D^* is used to define the domain of all tuples of D : $\langle \rangle$, $\langle D \rangle$, $\langle D, D \rangle$, ... *BasVal* and *BasCon* are fully defined in Section C.7.

```

<expr> ::= ...
          | <expr1> <op> <expr2>
          | <varid> <expr> ...
          | binary operator
          | function appl., n >= 1

2.3.6 Case Expressions

Case expressions must be complete in the sense that all possible values of the type of the expression which is discriminated on must be matched by one or more of the specified patterns. In determining whether an expression matches a pattern, the patterns are matched in order top-to-bottom, left-to-right. In matching a pattern, a variable or wildcard matches any value (in the former case also creating a new binding for the variable or wildcard to the matched sub-expression), any other pattern matches if the pattern constructor matches the expression's constructor and all sub-expressions match all corresponding sub-patterns. Patterns are left-linear (there are no repeated variables within a single pattern).

<expr> ::= ...
          | "case" <expr> "of"
          | <matches> ...
          | <match1> "in" ... "in" <matchn>
          | n >= 1

<match> ::= ...
          | <patt> "..." <expr>

Conditions can be seen as a special case of case-expressions where the expression being discriminated on has type bool and there are precisely two alternatives depending on whether the value of the expression is true or false.

          | "if" <expr1> "then" <expr2>
          | "else" <expr3>
          | conditional

2.3.7 Local Declarations

Local declarations are used to introduce one or more bindings of variables to expressions with a limited scope. The name introduced by a binding is visible within other bindings in the same set of declarations as well as within the target expression. All value bindings are evaluated before the body of the expression is evaluated.

<expr> ::= ...
          | "let" <valdecls> "<in>" <expr>
          | local definition

```

2.3.8 Type Expressions and Type Coercions

Types can be given to an expression using the "*in*" operator. In this case, the compiler will verify statically that the expression has the specified type, or can be "viewed" as the specified type. These operations are purely static and have no dynamic effect. More powerful dynamic type coercions can be specified using "*as*"-expressions. A table of types that are compatible for coercion purposes is given in Section 2.1.3. In this case, some computation

may be required to coerce a value from one type to another. Unlike the use of the “`as`” operator, a type coercion may not be reversible; information may be lost during the coercion process, for example. Coercions must therefore be treated with care.

B.7 Static Semantics: Types

`<expr>` ::= ...
| `<expr> ":" <exprtype>` type cast/view
| `<expr> "as" <exprtype>` type coercion

2.3.9 Exceptions

Exceptions can be raised in any expression. The exception is propagated immediately it is raised to the enclosing `box`, which must provide a handler to handle the exception.

`<expr>` ::= ...
| "raise" `<exnid> <expr>` raise an exception

2.3.10 Time and Space Constraints

Within-expressions are used to specify that evaluation of the associated expression must complete within the specified constraint (which must be a constant). Failure to do so causes an exception to be raised with a `0` if not given explicitly, this exception is one of `Timeout`, `StackOverflow` or `HeapOverflow` and must be handled by the box. It is raised with a `0` argument. If only one space constraint is specified, it represents a heap constraint, otherwise the first constraint represents a heap constraint, and the second a stack constraint.

`<expr>` ::= ...
| "within" `<constraint> ["raise" <exnid>]`

`<constraint>` ::= ...
| `timec ["n" spaces ["(" spacec "n" ")n"]]`
| `spacec ["(" spacec "n" ")n"]]`

2.3.11 Constant Expressions

In some places, expressions have a statically fixed value. This is indicated by `<cexpr>`. Such expressions may include variables, constructors, constants, and predefined operators on such values, but may not include user-defined function calls, raise expressions, timeouts or case/if/let expressions where any of the above rules are violated, or which use any non-constant variable identifiers other than as the sole result of the expression. The compiler will evaluate such expressions at compile-time and generate code to ensure that the appropriate value or variable is loaded in constant time at runtime.

`<cexpr>` ::= `<expr>`

2.3.12 Profiling and Verification

Two expression forms are used for profiling and cost verification purposes. `profile e` prints the costs of executing `e`, and returns the value of `e`. `verify e` applies the cost modeler to the expression `e` and checks that the actual costs are within those that are determined. A `StackOverflow` or `HeapOverflow` is raised as appropriate if the inferred costs are not achieved in practice. This is mainly useful to eliminate errors during the development of the cost modelling software.

B.8 Static Semantics: The Initial Environment

$\boxed{E \vdash \tau}$

(59)

(60)

$$\frac{(AE \text{ of } E) \alpha = n \quad \forall i, 1 \leq i \leq n, E \vdash \tau_i}{E \vdash \alpha} \quad (61)$$

(61)

(62)

$\boxed{E \vdash \tau \Rightarrow \sigma}$

(63)

$$\frac{E \vdash \tau \Rightarrow \sigma \quad E \vdash \tau' \Rightarrow \sigma}{E \vdash \tau \rightarrow \tau' \Rightarrow \sigma} \quad (64)$$

$E \oplus_{AE} \{\alpha_1, \dots, \alpha_n\} \vdash \tau$

$E \vdash \vee \alpha_1 \dots \alpha_n \cdot \tau$

+

The initial environment used in the static semantics comprises type bindings for all values defined in the module `Prfdata`, including functions, data constructors, type constructors and exceptions, plus bindings for basic values as given below.
The initial variable environment contains types for the following functions (`#as Val`):

`PrimPlusInt` \rightarrow `Int` \rightarrow `Int`

`PrimMultInt` \rightarrow `Int` \rightarrow `Int`

...

plus types for the standard constructors (`BasCn`):
`0` \rightarrow `Int`, `1` \rightarrow `Int`, `0,0` \rightarrow `Float`, `0,1` \rightarrow `Float`, `...,True` \rightarrow `Bool`, `False` \rightarrow `Bool`, `'a` \rightarrow `Char`, ..., `(i)` \rightarrow `V`, `α` \rightarrow `List α`, `Nil` \rightarrow `List α`

$$\frac{\forall i, 1 \leq i \leq n, E \vdash pat_i \Rightarrow \tau, VE_i}{E \vdash \langle pat_1, \dots, pat_n \rangle \Rightarrow \text{Vector } \tau, \bigoplus_{i=1}^n VE_i} \quad (52)$$

B.5.1 Static Semantics: Exception Handler Matches

$$\frac{E \vdash \text{exnid} \Rightarrow \text{Exn } \tau \quad E \vdash \text{pat} \Rightarrow \tau, VE \quad E \stackrel{\exists}{\vdash} \forall \nu:VE \vdash \text{exp} \Rightarrow \tau'}{E \vdash \text{exnid pat} \rightarrow \text{exp} \Rightarrow \tau'} \quad (53)$$

$$\frac{\begin{array}{c} E \vdash \text{handler} \Rightarrow \tau \quad E \vdash \text{handlers} \Rightarrow \tau \\ \hline E \vdash \text{handler} \mid \text{handlers} \Rightarrow \tau \end{array}}{E \vdash \text{tyvar} \Rightarrow \alpha} \quad (54)$$

B.6 Static Semantics: Type Expressions

$$\boxed{E \vdash \text{type} \Rightarrow \tau}$$

$$\frac{\begin{array}{c} (\text{VE of } E) \text{ (tyvar)} = \alpha \\ \hline E \vdash \text{tyvar} \Rightarrow \alpha \end{array}}{E \vdash \text{tyvar} \Rightarrow \alpha} \quad (55)$$

$$\frac{(\text{VE of } E) \text{ (tycon)} = \forall \alpha_1 \dots \alpha_n. \lambda \alpha_1 \dots \alpha_n. \quad \forall i, 1 \leq i \leq n, E \vdash \text{type}_i \Rightarrow \tau_i}{E \vdash \text{tycon type}_1 \dots \text{type}_n \Rightarrow \chi \tau_1 \dots \tau_n} \quad (56)$$

$$\frac{E \vdash \text{type} \Rightarrow \tau \quad E \vdash \text{type} \Rightarrow \tau'}{E \vdash \text{type} \rightarrow \text{type}^* \Rightarrow \tau \rightarrow \tau'} \quad (57)$$

$$\frac{E \vdash \text{type} \Rightarrow \tau \quad E \vdash \text{type} \Rightarrow \tau'}{E \vdash (\text{type}) \Rightarrow \tau} \quad (58)$$

$$\begin{aligned} \langle \text{expr} \rangle &::= \dots \\ &\quad | \text{ "profile" } \langle \text{expr} \rangle \\ &\quad | \text{ "verify" } \langle \text{expr} \rangle \end{aligned}$$

Note that these may not be supported in all implementations.

2.4 The Coordination Layer

This section describes the Hume coordination layer and the wiring metalinguage. The formal dynamic semantics of Hume boxes is given in Appendix C.

2.4.1 Boxes

The Hume unit of coordination is the *box*. A box has a unique name, specified in its *prelude*. A box has *inputs* and *outputs* termed *ins* and *outs*. Ins and outs are fixed width sequences of *inout* type. An *inout* type is any Hume type excluding a function or exception. A box's *ins* and *outs* are specified in its prelude. Each *in* and *out* has a unique name, and is typed. The exceptions a box handles are specified in the box's prelude. It is possible to provide a within-clause to limit costs within a box execution in the same way as they are limited in an expression.

$$\begin{aligned} \langle \text{boxdecl} \rangle &::= \langle \text{prelude} \rangle \langle \text{body} \rangle \\ \langle \text{prelude} \rangle &::= \\ &\quad | \text{ "box" } \langle \text{boxid} \rangle \\ &\quad | \text{ "in" } \langle \text{inoutlist} \rangle \\ &\quad | \text{ "out" } \langle \text{inoutlist} \rangle \\ &\quad | \text{ "within" } \langle \text{constraint} \rangle \\ &\quad | \text{ "handles" } \langle \text{exnidlist} \rangle \quad] \\ \langle \text{inoutlist} \rangle &::= \\ &\quad | \text{ "inout" } \text{ " } \dots \text{ " } \text{ " } \text{ " } \langle \text{inout} \rangle \quad n \geq 1 \\ \langle \text{inout} \rangle &::= \\ &\quad | \text{ "varid" } \text{ " : } \langle \text{exprtype} \rangle \text{ ["timeout" } \langle \text{expr} \rangle \text{] } \end{aligned}$$

Each unique stream or port may be associated with only one box.

2.4.2 Box Bodies

The body of a box consists of a set of matches against input values, an optional timeout covering all the matches, plus the exception handlers that apply during each iteration of the body.

$$\begin{aligned} \langle \text{body} \rangle &::= \\ &\quad | \text{ "match" } | \text{ "fair" } \\ &\quad | \text{ "matches" } \\ &\quad | \text{ "timeout" } \langle \text{expr} \rangle \\ &\quad | \text{ "handle" } \langle \text{handlers} \rangle \quad] \end{aligned}$$

Each *match* in a box must have:

1. a pattern component *<pat>* which is type consistent with the *in* declaration; and

2. an expression component <expr> which is type consistent with the out declaration.

Top-level patterns may include *s. The purpose of a * is to indicate that the corresponding input is neither matched nor consumed.

Matching may be either sequential (infix) or "fair". Rules introduced by the match keyword are matched in order from top to bottom. The first rule (if any) that fully matches the inputs is selected. Thus a single rule may be matched repeatedly if the same inputs are encountered. In some cases, this can result in certain rules never being used. Fair matching, in contrast, guarantees that all rules are given an equal probability of being matched.

2.4.3 Exception Handlers

There must be a <handler> for each exception specified in the box's handles clause. All non-system exceptions that can be raised by any expression within the body of the box, or which occur through input timeouts, must be handled by an explicit handler. No handler can perform any computation.

```
<handlers> ::= <handler1> | "..." | "<>handler_n>" n >= 1

<handler> ::= <expr>
<expr> ::= <expr> "=>" <expr>

<handler> ::= <pat1> ... <patn> n >= 1
```

Every <handler> in a box must have:

1. a <handleref> corresponding to an entry in the handles declaration; and
2. a <handleref> which is type consistent with the out

2.4.4 Wiring

Boxes are wired together by specifying for each *in* or *out*, the corresponding source or destination box's *in* or *out*, or a stream, or a port, to which it is connected. Wires may either be specified for a complete set of box sources and destinations or individually for each input/output pair.

```
<wiringdecl> ::= "wire" <boxid> <sources> <dests>
                  | "wire" <link> "to" <link>
<sources>/<dests> ::= "(" <link1> "..." " " <linkn> ")" n >= 0
<link> ::= <connection>
          | <strid>
          | <portid>
<connection> ::= <boxid> " " <varid>
```

Connection to another box is specified by that box's name extended with the *in* or *out* name. Boxes may be wired to themselves.

$$\frac{\begin{array}{c} \text{E} \vdash \text{exp} \Rightarrow \tau \\ \text{E} \vdash \text{verify exp} \Rightarrow \tau \end{array}}{\text{E} \vdash \text{exp} \Rightarrow \tau} \quad (43)$$

$$\frac{\begin{array}{c} \text{E} \vdash \text{exp} \Rightarrow \tau \\ \text{E} \vdash (\text{exp}) \Rightarrow \tau \end{array}}{\text{E} \vdash (\text{exp}) \Rightarrow \tau} \quad (44)$$

B.5 Static Semantics: Matches

$$\frac{}{\boxed{\text{E} \vdash \text{match} \Rightarrow \tau}} \quad (45)$$

$$\frac{\begin{array}{c} \text{E} \vdash \{ \text{match} \} \Rightarrow \tau \\ \text{E} \vdash \{ \text{matches} \} \Rightarrow \tau \end{array}}{\text{E}, v \vdash \{ \text{match} | \text{matches} \} \Rightarrow \tau} \quad (46)$$

$$\frac{\begin{array}{c} \forall i, 1 < i \leq n, \text{ E} \vdash \text{match}_i \Rightarrow \tau_i, \text{VE}_i \\ \text{E} \oplus_{V_E} (\bigoplus_{i=1}^n \text{VE}_i) \vdash \text{exp} \Rightarrow \tau' \end{array}}{\text{E} \vdash \{ \text{pat}_1 \dots \text{pat}_n \Rightarrow \text{exp} \} \Rightarrow \tau_1 \dashv \dots \dashv \tau_n \dashv \tau'} \quad (47)$$

$$\frac{}{\boxed{\text{E} \vdash \text{pat} \Rightarrow \tau, \text{VE}}} \quad (48)$$

$$\frac{}{\text{E} \vdash \{ \text{var} \mapsto \tau, \{ \} \}} \quad (49)$$

$$\frac{\text{E} \vdash \{ \text{var} \mapsto \tau, \{ \} \}}{\text{E} \vdash \text{var} \Rightarrow \tau, \{ \text{var} \mapsto \tau \}} \quad (50)$$

$$\frac{}{\boxed{\forall i, 1 < i \leq n, \text{ E} \vdash \text{pat}_i \Rightarrow \tau_i, \text{VE}_i}} \quad (51)$$

$\forall i. 1 < i \leq n, E \vdash \exp_i \Rightarrow \tau_i$	$E \vdash (\exp_1, \dots, \exp_n) \Rightarrow \text{Tuple}_n \tau_1 \dots \tau_n$	(32)
$E \vdash \langle < > \rangle \Rightarrow \text{Vector } \tau$		(33)
$\forall i. 1 < i \leq n, E \vdash \exp_i \Rightarrow \tau$	$E \vdash \text{case exp of match} \Rightarrow \tau \rightarrow \tau'$	(34)
$E \vdash \exp \Rightarrow \tau$	$E \vdash \text{if exp}_1 \text{ then exp}_2 \text{ else exp}_3 \Rightarrow \tau$	(35)
$E \vdash \text{deccls} \Rightarrow E'$	$E \vdash \text{deccls in exp} \Rightarrow \tau$	(36)
$E \vdash \exp_1 \Rightarrow \text{Bool}$	$E \oplus E' \vdash \exp \Rightarrow \tau$	(37)
$E \vdash \text{type} \Rightarrow \tau$	$E \vdash \text{let decls in exp} \Rightarrow \tau$	(38)
$E \vdash \exp \Rightarrow \tau'$	$E \vdash \exp \text{ as type} \Rightarrow \tau'$	(39)
$E \vdash \exp \Rightarrow \tau$	$E \vdash \text{raise exnid exp} \Rightarrow \tau'$	(40)
$E \vdash \exp_2 \Rightarrow \text{Time}$	$E \vdash \exp_1 \Rightarrow \tau$	(41)
$E \vdash \text{profile exp} \Rightarrow \tau$	$E \vdash \exp_1 \text{ within } \exp_2[\text{raiseexnid}] \Rightarrow \tau$	(42)

2.4.5 Box Templates and Instantiation

A template can be defined to give the structure of a box, which is then instantiated to produce a number of boxes.

$$\begin{array}{l} t \cdot \text{tmpl_tck} \\ \quad \langle \text{tmpldecl} \rangle ::= \\ \quad \quad \langle \text{template} \rangle \langle \text{tmplatid} \rangle \langle \text{prelude} \rangle \langle \text{body} \rangle \end{array} \quad (32)$$

To simplify the construction of complex systems, both boxes and templates may be replicated to give new boxes. The box/template may be replicated either once or a number of times (indicated by * <intconst>). For example, instantiate t as b * 4 will introduce boxes b1, b2, b3 and b4[expr-inroduced].

$$\begin{array}{l} t \cdot \text{tmpldecl} \\ \quad \langle \text{wiringdecl} \rangle ::= \\ \quad \quad \langle \text{replicate} \rangle \langle \text{boxid} \rangle \text{as} \langle \text{boxid} \rangle [\text{"*"} \langle \text{intconst} \rangle] \\ \quad \quad \mid \langle \text{instantiate} \rangle \langle \text{templateid} \rangle \text{as} \langle \text{boxid} \rangle [\text{"*"} \langle \text{intconst} \rangle] \end{array} \quad (33)$$

2.4.6 Wiring Macros

Wiring macros can be introduced by associating a wiring definition with a name and set of parameter names. The parameter names declared on the LHS of the RHS of the wiring macro and substitute the corresponding concrete name.

$$\begin{array}{l} \langle \text{wiringdecl} \rangle ::= \\ \quad \langle \text{wire} \rangle \langle \text{macroid} \rangle " \langle id1 \rangle \dots \langle idn \rangle " \text{=} \langle \text{wired} \rangle \langle \text{sources} \rangle \langle \text{dsts} \rangle \\ \langle \text{wiringdecl} \rangle ::= \\ \quad \langle \text{wiringdecl} \rangle \text{,} \\ \quad \langle \text{wiringdecl} \rangle ::= \\ \quad \langle \text{wire} \rangle \langle \text{macroid} \rangle " \langle id1 \rangle \dots \langle idn \rangle " \text{=} \langle \text{wired} \rangle \langle \text{args} \rangle \end{array} \quad (34)$$

The macros are used in place of normal wiring declarations

$$\langle \text{wiringdecl} \rangle ::= " \langle \text{wiring} \rangle \langle \text{macroid} \rangle \langle \text{args} \rangle" \quad (35)$$

Depending on usage, these arguments may be either box names or names of inputs/outputs. It is not possible to use unrestricted values such as integers as arguments to wiring macros. For example, we can generate a wiring macro Track that is instantiated to wire a number of boxes with identical inputs and outputs in series as follows.

```
constant RingSize = 8;
macro predR i = (i-1) % RingSize;
macro succR i = (i+1) % RingSize;
wire Track ( this, prev, next ) =
  wire {this} { {this}.value , {prev}.outval, {next}.inval }
    { {this}.value , {next}.outval, {prev}.inval }
  ;
for i = 0 to RingSize
  wire Track ( Ring{i} ), Ring{predR(i)}, Ring{succR(i)}
  ;
```

2.4.7 Repeated Wiring

Wiring declarations can be repeated under the control of a variable (optionally omitting certain values).

```

<wiringdecl> ::= "for" <id> "=" <expr> "to" <expr> { "except" <exprs> }
    <wiringdecl>

```

The repetition variable may be used within the wiring declaration (enclosed within braces), where it takes on each value in the iterator clause in turn. For example,

```

for i = 0 to 4 except (2, 1)
    instantiate Track as Ring[i];

```

will generate Ring0, Ring3, Ring3 as instances of the Track template. It is possible to nest for-loops if required, and it is possible to use both loop variables, static constants and expression macros in the expressions. Note that such loops are part of the static coordination layer designed to create a static process network rather than part of the dynamic expression language.

2.4.8 Initial Values

It is possible to specify initial values for wires. These may be provided either as part of the link specification for a wire or using an explicit initial declaration.

```

<wiringdecl> ::= ...
    | "initial" <wireids> <inits>
<inits> ::= "({" <init1> "," ... "," <initn> ")" n >= 1
<init> ::= <wireids> "=" <expr>
<linkprop> ::= ...
    | "initialy" <expr>

```

For example, we can provide an initialiser for the value input of the Ring{Train1Pos} box as shown below. Initialisers may be provided either on input or output wires, as convenient. It is, however, an error for more than one initialiser to be provided for any wire.

```
initial Ring {Train1Pos} { value = Just "Train1" };
```

2.4.9 Expression Macros

Expression macros are used to construct simple compile-time macros that are resolved during construction of the static process network.

```

<wiringdecl> ::= ...
    | "macro" <mid> <ids> "=" <expr>

```

2.4.10 I/O Declarations

Interactions with the operating system and devices are specified in the declaration language.

```

<decl> ::= ...
    | "stream" <loade>

```

B.4 Static Semantics: Expressions

The first rule generalises the types of expressions from monotypes to polytypes. The second determines the type of a variable using the variable environment.

$$\boxed{E \vdash \text{exp} \Rightarrow \sigma}$$

$$\frac{(\forall E. \phi(E))(\text{id}) \approx \sigma}{E \vdash \text{id} \Rightarrow \sigma} \quad (23)$$

$$\frac{E \vdash \text{exp} \Rightarrow \tau \quad E \vdash \tau \Rightarrow \sigma}{E \vdash \text{exp} \not\Rightarrow \tau \quad \text{exp} \not\approx \text{id}} \quad (24)$$

$$\boxed{E \vdash \text{exp} \Rightarrow \tau}$$

$$\frac{E \vdash \text{id} \Rightarrow \forall \alpha_1 \dots \alpha_n. \tau \quad \forall i. 1 < i \leq n, E \vdash \tau_i}{E \vdash \text{id} \Rightarrow \tau[\tau_1/\alpha_1, \dots, \tau_n/\alpha_n]} \quad (25)$$

$$\frac{E \vdash \text{char} \Rightarrow \text{String}}{E \vdash \text{string} \Rightarrow \text{Char}} \quad (26)$$

$$\frac{E \vdash \text{con}/\text{var} \Rightarrow \tau_1 \dots \dots \tau_n \rightarrow \tau' \quad \forall i. 1 < i \leq n, E \vdash \text{exp}_i \Rightarrow \tau_i}{E \vdash \text{con}/\text{var} \exp_1 \dots \exp_n \Rightarrow \tau'} \quad (27)$$

$$\frac{E \vdash \forall i. 1 \leq i \leq n, E \vdash \text{exp}_i \Rightarrow \tau \Rightarrow \text{List } \tau \quad n \geq 1}{E \vdash [\exp_1, \dots, \exp_n] \Rightarrow \text{List } \tau} \quad (28)$$

$$\frac{E \vdash \{\} \Rightarrow \text{List } \tau}{E \vdash \{\} \Rightarrow \text{Tuple}_0} \quad (29)$$

$$\boxed{E \vdash \{\} \Rightarrow \text{Tuple}_0} \quad (30)$$

$$\boxed{E \vdash \{\} \Rightarrow \text{Tuple}_0} \quad (31)$$

B.3 Static Semantics: Programs and Wiring

$\langle \text{iodes} \rangle ::= \langle \text{ioid} \rangle \langle \text{from} \rangle \langle \text{to} \rangle \langle \text{string} \rangle$

$E_0 \oplus v_E \quad 1E \vdash \text{decls} \Rightarrow E$	$((E_0 \oplus v_E) \oplus v_E \quad 1E) \oplus v_E \quad SE \vdash \text{boxes} \Rightarrow VE \quad VE \vdash \text{wires}$	(17)
	$\frac{}{\vdash \text{Program} \text{ decls boxes wires}}$	
	$\boxed{E \vdash \text{boxes} \Rightarrow VE}$	
	$\frac{Vi, 1 \leq i \leq n, \vdash \text{box}_i \Rightarrow VE_i}{\vdash \text{box}_1 \dots \text{box}_n \Rightarrow \bigoplus_{i=1}^n VE_i}$	(18)
	$\boxed{\vdash \text{box} \Rightarrow VE}$	
	$\frac{E \vdash \text{body} \Rightarrow \tau \rightarrow \tau' \quad E \vdash \text{ins} \Rightarrow \tau \quad E \vdash \text{outs} \Rightarrow \tau' \quad E \vdash \tau \rightarrow \tau' \Rightarrow \sigma}{\vdash \text{box} \text{ boxd ins outs body} \Rightarrow \{ \text{boxd} \mapsto \sigma \}}$	(19)
	$\boxed{E \vdash \text{wires}}$	
	$\frac{\forall i, 1 \leq i \leq n, \vdash \text{wire}_i}{\vdash \text{wire}_1 \dots \text{wire}_n}$	(20)
	$\boxed{\vdash \text{wire}}$	
	$\frac{E \vdash \text{sources} \Rightarrow \tau \quad E \vdash \text{dests} \Rightarrow \tau' \quad E \vdash \text{boxid} \Rightarrow \tau \rightarrow \tau'}{\vdash \text{wire boxid sources dests}}$	(21)
	$\boxed{E \vdash \text{body} \Rightarrow \tau}$	
	$\frac{E \vdash \text{time} \Rightarrow \tau \quad E \vdash \text{matches} \Rightarrow \tau \rightarrow \tau' \quad E \vdash \text{handlers} \Rightarrow \tau \rightarrow \tau'}{E, vs \vdash \text{time matches handles} \Rightarrow \tau \rightarrow \tau'}$	(22)

The string is a system-specific designator identifying the operating system entity (file, device etc.) that the port or stream is attached to. Semantically, a stream differs from a port in that the latter may be read from or written to repeatedly, whereas the former is read from or written to once only.

Each stream or port must be wired to precisely one *in* or *out*. An *in* may be mentioned in only one *dests*. An *out* may, however, be mentioned in more than one *source*.

The type of a *<connection>/<stream>/<port>* must match that of the *in* or *out* with which it is associated. Only outputs of boxes or ports/stream that are attached using input (*from*) designators can be wired to *<sources>*. Conversely, only inputs to boxes or ports/stream that are attached using output (*to*) designators can be wired to *<dests>*.

Appendix A

Syntax

This appendix gives a BNF definition of the concrete syntax for Hume programs. The meta-syntax is conventional. Terminals are enclosed in double quotes " ... ". Non-terminals are enclosed in angle brackets < ... >. Vertical bars | are used to indicate alternatives. Constructs enclosed in brackets [...] are optional. Parentheses (...) are used to indicate grouping. Ellipses (...) indicate obvious repetitions. An asterisk (*) indicates zero or more repetitions of the previous element, and a plus (+) indicates one or more repetitions.

Programs and Modules

```

<program> ::= 
    "program" <deccls>
  | <deccls>

<module> ::= 
    "<module>" <modids> "<where>" <deccls>
  | <deccls>

```

Declaration Language

```

<deccls> ::= 
    <deccls> <modid> "i" ... "i" <declns>   n >= 1

$E \vdash \text{export var}_1 \dots \text{var}_n \Rightarrow \{ \}, \{ \}$

B.2 Static Semantics: Declarations

Declarations are processed to generate a *variable environment* (VE) mapping identifiers to types, and a *type environment* (TE) recording the arity of type constructors. Declarations may be self-recursive or mutually recursive.

$$\boxed{E \vdash \text{decis} \Rightarrow E}$$

$\forall i, 1 \leq i \leq n, E \oplus \bigoplus_{j=1}^n E_j \vdash \text{decl}_i \Leftrightarrow VE_i, TE_i$	$E \vdash \text{decl}_1 \dots \text{decl}_n \Leftrightarrow E \oplus VE \left(\bigoplus_{i=1}^n VE_i \right) \oplus TE \left(\bigoplus_{i=1}^n TE_i \right)$	$E \vdash \text{decl} \Rightarrow VE, TE$
		$\boxed{E \vdash \text{decl} \Rightarrow VE, TE}$
$E \vdash \text{type} \Rightarrow \tau \quad E \vdash \tau \Rightarrow \sigma$	$E \vdash \text{foreign import } [s c] \mid \text{str} \mid \text{var} :: \text{type} \Rightarrow \{ \text{var} \mapsto \sigma \}, \{ \}$	(1)
		(2)
$E \vdash \text{var} :: \sigma \quad E \vdash \text{type} \Rightarrow \tau \quad E \vdash \tau \Rightarrow \sigma$	$E \vdash \text{foreign export } [c] \mid \text{str} \mid \text{var} :: \text{type} \Rightarrow \{ \}, \{ \}$	(3)
		(4)
$E \vdash \text{exp} :: \sigma$	$E \vdash \text{foreign import } [safety] \mid \text{callconv} \mid \text{foreign export } [safety]$	
		(5)
$E \vdash \text{constant var} :: \text{exp} \Rightarrow \{ \text{var} \mapsto \sigma \}, \{ \}$	$E \vdash \text{callconv} :: \{ \text{ccall} \mid \text{stdcall} \mid \text{cplusplus} \mid \text{jvna} \mid \text{dotnet} \}$	
		(6)
$(\text{SE of } E) \text{ var}^* :: V a_1 \dots a_n, \tau \quad [E \vdash \text{expr} \Rightarrow \tau]$	$E \vdash \text{Port } \tau / \text{Stream } \tau / \text{Memory } \tau / \text{Fifo } \tau / \text{Interrupt } \tau \Rightarrow \sigma$	
		(7)

Types

$\text{exprtype} ::=$	basetype	base type
	$\text{vector} < \text{initconst} >$	$\text{of } <\text{type}>$ vector
	$\{ \}$	empty tuple
	$\{ [\text{type}] \mid \text{types} \}$	list
	$\{ \text{type} \mid \text{type} \}$	discr. union, $n \geq 0$

```

constant expression

Appendix B

Static Semantics

This appendix defines the static semantics of Hume, giving formal type rules etc.

B.1 Static Semantics: Notation

Except where noted, we use the same notation as the definition of Standard ML [2].

Our static semantics is given in terms of the semantic domain SemVal defined below. The notion $D(k)$ is used to denote a sequence of k instances of $D, DD, \dots, D D^{k-1}$.

BasVal and BasCon are fully defined in Section B.8. The function coercable is defined with reference to the table in Section 2.1.3.

$\text{BasVal} =$	$\{ (+), (=:=), \dots \}$	Basic Values
$\text{BasCon} =$	$\{ (), \text{Nil}, \text{True}, \text{False}, \dots \}$	Basic Constructors
$\text{Con} =$	$\{ \text{BasCon} + \text{con} \}$	Constructors
$\text{Var} =$	$\{ \text{BasVal} + \text{var} \}$	Variables
$\text{id} \in$	$\{ \text{VarEnv}, \text{TyVarEnv} \}$	Identifiers
$E, E' \in$	$\{ \text{VarEnv}, \text{SE} \in \text{VarEnv} \cup \{ \text{var} \mapsto \text{PolyType} \} \}$	Environments
$\text{IE}, \text{VE}, \text{VE}' \in$	$\{ \text{TypeEnv} \cup \{ \chi \} \}$	Variable Environments
$\text{TE} \in$	$\{ \text{TyVarEnv} \cup \{ \alpha \} \}$	Type Environments
$\text{AE} \in$	$\{ \text{TyVarEnv} \}$	Type Variable Environments
$\alpha, \beta \in$	$\{ \text{TyVar} \}$	Type Variables
$\chi \in$	$\{ \text{TyCon} \}$	Type Constructors
$\tau, \tau' \in$	$\{ \text{Type} \equiv \text{TyVar} + \text{TyConType}(\kappa) \cup \text{Type} \rightarrow \text{Type} \}$	Monomorphic Types
$\sigma, \sigma' \in$	$\{ \text{PolyType} \equiv \text{V TyVar}(\kappa), \text{Type} \}$	Polymorphic Types

Environments are unique maps. They are used by applying the environment to an identifier to give the corresponding entry in the map, for example if E is the environment $\{ \text{var} \mapsto \text{v} \}$, then $E(\text{var}) = \text{v}$. The $m_1 \oplus m_2$ operation updates an environment mapping m_1 by the new mapping m_2 . The domains of m_1 and m_2 must be disjoint (this introduces an implicit side-condition on each semantic rule that uses the \oplus operation). The $m_1 \ominus m_2$ operation is similar, but allows values in m_1 to be “shadowed” by those in m_2 . It is therefore unnecessary for the domains of m_1 and m_2 to be disjoint. There are two degenerate environments, type environments (which are sets of type constructors) and type variable environments (which are sets of type variables). These environments simply record the presence or absence of their components in the environment, and are used as $\text{TE}(\chi)$, for example. Where an environment contains sub-environment, the notation $E' E$ is used to select the sub-environment E' from E . The notation $E \oplus_E E'$ updates subenvironment E' of E with the value E' .
